

RNA splice-junction evidence: useful results and false-lead checks

A. MET: no observed exon-14-skipping junction

Zero skipping support also holds before anchor filtering; inclusion has 169 / 150 reads.
This is a bounded negative for this exact junction, not a validated clinical exclusion.

B. BAP1: the frameshift is physically linked to canonical splicing

Direct links require the deletion and junction in the same read (mates collapsed by name).
Local mutant-spliced RNA support does not establish a full isoform, protein or HLA display.

C. APC: the strongest GENCODE37-unannotated event is a natural isoform

This matches the established APC exon-9a splice form, r.934_1236del.

*Exon 10 in the selected transcript includes the historical coding-exon-9 region.
